EP 0 544 298 B1

Description

BACKGROUND OF THE INVENTION

5 1. Field of the Invention

This invention relates to a method for the lubrication of an automatic transmission of a motorcar comprising lubricating the automatic transmission with an automatic transmission fluid composition, and more particularly a method comprising lubricating the transmission with an automatic transmission fluid composition which is excellent in shift
10 feeling as well as prevention of slip after contacting the clutch, and in addition which has a short shift time and a very small change in the friction coefficient during use.

2. Background Art

15 An automatic transmission is a transmission having such a mechanism in which the transmission torque ratio is automatically established in response to the speed of the car, magnitude of load or the like. Such an automatic transmission comprises a torque converter part, a multiple disk clutch, a planetary gear part, and a hydraulic controlling part. Automatic transmission fluid is a common lubricating oil for all the parts described above, and which functions as a transfer fluid for motive power, as a lubricating oil for gears and bearings, and as a hydraulic fluid for controlling
20 devices.

Such a shift operation wherein various reduction gear ratios are attained by changing the connections between the respective members of planetary gears is carried out by utilizing clutches and a braking band. At the present time, the general type of clutch is a wet clutch composed of a multiple disk clutch comprising a driven plate of steel and a drive plate of a paper frictional material. Frictional properties of such a wet clutch greatly influence the transmitting
25 function of the automatic transmission unit, and in turn, the shift feeling of the motorcar.

While frictional properties of the wet clutch change depending upon the combination of the paper frictional material being the drive plate and the automatic transmission fluid, the influence due to composition of the automatic transmission fluid is remarkable; therefore, in recent years, in view of smoother shift feeling, there is a tendency to lay stress on the frictional properties of automatic transmission fluid in wet clutch, and a need exists for an automatic transmission
30 fluid having good frictional characteristics.

Such frictional properties are evaluated by a SAE No. 2 friction tester, which is well known by those skilled in the art. This type of tester is essentially an inertia dynamometer wherein the kinetic energy of a rotor is spent by a frictional plate, and a coefficient (μ) of friction is calculated from the friction torque.

As methods for measuring coefficient of friction, there are the dynamic method and the static method. The dynamic method is effected in such a manner that an inertia plate (mounted on a motor shaft) is rotated at a high speed by
35 means of a motor for a given period of time, thereafter the motor power supply is shut off, and at the same time pneumatic pressure is applied to a piston, whereby the driven plate is pressed against the drive plate which has been rotated integrally with the motor shaft to stop the movement of the inertia plate. A dynamic friction coefficient (μ_d) at the time of rotating the motor is obtained from the friction torque curve in the above case. Furthermore a friction coefficient at the end of clutch engaging (μ_o) is obtained from the friction torque immediately before the stop.

In the static method, the friction torque produced by a facing up of the drive plate and the driven plate is obtained by rotating the inertia plate by means of an auxiliary motor at a very low speed while applying pneumatic pressure to the piston. The static breakaway friction coefficient (μ_s) is calculated from the value obtained as described above.

In general, a larger value of μ_d is desired in view of a short shift time, and a larger value of μ_s is desired in view of the more effective prevention of slip after contacting the clutch. On the other hand, a value of μ_o/μ_d closer to 1.0 provides a smoother shift feeling, and is thus desirable. In recent years, there is a tendency in demand for an automatic transmission fluid having a much higher value of both the coefficients of friction (μ_d and μ_s), because such a fluid leads to motorcars equipped with lightweight and small-sized transmission clutches, and such cars will give better fuel economy.

50 Regarding the disclosure of pertinent prior art references, in, e.g., the WO-A-9 109 922 are disclosed lubricant compositions comprising

- A.) a major amount of an oil of lubricating viscosity,
- B.) a borated metal salt of an organic acid,
- 55 C.) at least one polysulphide-containing organic composition,
- D.) at least one phosphorous-containing composition.

Additionally, the disclosed compositions may contain other additives E.), F.), and G.), especially in form of friction

modifiers, copper corrosion inhibitors, phase separating preventors, etc.
However, no accurate values for the friction coefficients μ_s , μ_d and μ_o/μ_d , being most relevant for any technical effect or application of a lubricant are disclosed or discussed by the authors of this prior art reference.

Furthermore, the reference EP-A-O 447 916 of the Applicant himself discloses engine oil compositions, comprising:

5

- A.) a major amount of a lubricating base oil,
- B.) 0,01 - 30 % overbasic, oil-soluble metal salt,
- C.) 0,01 - 5 % of an antioxidant, including e.g. phenoles, amines, sulfur compounds, zinc thiophosphates, pheno-
- thiazines, etc.,
- 10 D.) 0,01 - 5 % of a friction modifier, including e.g. molybdenum dithiophosphates, molybdenum dithiocarbamates, molybdenum disulfides, fluorocarbons, boric acid esters, alkylamines, higher alcohols, higher fatty acids, fatty acid esters, fatty acid amides.

10

However, the whole composition as disclosed therein does not comprise any friction modifier having a long-chain alkyl group and an amino group in its molecule.

15

The reference WO-A-8 804 684 describes a lubricant mixture comprising:

20

- A.) boronated overbased alkaline-earth metal salts or alkali metal salts,
- B.) friction modifier, selected from the group comprising: fatty phosphites, fatty acid amides, boronated fatty epox-
- ides, fatty amines, glycerol esters and their boronated derivatives, boronated alkoxyated fatty amines, sulfurized
- olefins and mixtures thereof.
- C.) an oil of lubricating viscosity.

25

However, this document emphasizes, that the best results in respect to the technical applicability of a lubricant composition according to the state of the art will be accomplished by the use of a boron compound in both components A.) and B.), since only in that way the reduction of the dynamic coefficient, which is not desirable, can be compensated. A technical teaching corresponding to the use of only one boron-containing component was neither discussed nor suggested.

30

Furthermore, no values for the most important friction coefficients μ_s , μ_d and the ratio μ_o/μ_d , which generally influence the technical applicability of a lubricant most strongly are disclosed by this prior art reference.

The reference EP-A-O 407 124 discloses a lubricating oil composition, containing:

35

- A.) a base oil,
- B.) a phosphoric acid ester, phosphorous acid ester, phosphoric acid ester amine salt or phosphorous acid ester amine salt,
- C.) an aliphatic dicarboxylic acid compound, and alternatively
- D.) an alkylamine compound and/or succinimide or perbasic magnesium or calcium sulfonate.

40

However, this lubricant composition does not comprise an overbasic, oil-soluble metal salt. Furthermore, the friction coefficients as achieved according to the technical teaching of this prior art reference are comparatively low (see table 1-1 on page 9).

Hence, this disclosure also does not provide or suggest to the man skilled in the art any informations regarding to the technical problem on which the the present invention was based.

45

However, presently available automatic transmission fluids are less than satisfactory for good frictional properties.

SUMMARY OF THE INVENTION

50

One object of the present invention is to provide a method for the lubrication of an automatic of a motorcar comprising lubricating the automatic transmission with an automatic transmission fluid composition wherein both the coefficients of friction (μ_d and μ_s) are much higher than those of the conventional automatic transmission fluid composition, the ratio (μ_o/μ_d) of the coefficient of friction at the end of clutch engaging to the coefficient of dynamic friction is close to 1, and besides there is a very small change in both friction coefficients during use of the composition. This composition is hereinafter denoted as the composition of the present invention or as the composition for use in the method according to the present invention.

55

Furthermore, the automatic transmission fluid composition comprises 0.01 to 20 % by weight of an overbasic oil-soluble metal salt (a) prepared by use of an alkaline-earth metal borate, and 0.01 to 15% by weight of a compound (b) having a long-chain alkyl group and an amino group in the same molecular structure, on the basis of the total amount of composition as essential components, the balance being lubricating base oil.

Either mineral oils or synthetic oils may be used as the lubricating base oils in the composition of the present invention. Any paraffinic or naphthenic lubricating base oils, which have been used in a conventional automatic transmission fluid, are acceptable. Such lubricating base oils are usually manufactured by a process comprising topping crude oil followed by vacuum distillation, and refining the resulting lubricating oil fraction by a method selected from the group consisting of solvent deasphalting, solvent extraction, hydro-cracking, solvent-dewaxing, catalytic-dewaxing, hydro-refining, sulfuric acid treating, clay treating and the like.

Typical examples of the synthetic oils include poly- α -olefins such as polybutenes, octene-1 oligomers, decene-1 oligomers and the like; alkylbenzenes; alkylnaphthalenes; diesters such as ditridecyl glutarate, di-2-ethylhexyl adipate, diisodecyl adipate, ditridecyl adipate, di-3-ethylhexyl sebacate and the like; polyol esters such as trimethylolpropane caprylate, trimethylolpropane pelargonate, pentaerythritol 2-ethylhexanoate, pentaerythritol pelargonate and the like; polyoxyalkylene glycols; polyphenyl ethers; silicon oils; perfluoroalkyl ethers and the like.

As for these base oils, it is possible to use any single material or admixture consisting of two or more components which satisfy a kinematic viscosity of 1 to 10 cst, preferably 2 to 6 cst at 100°C.

The overbasic oil-soluble metal salts (a) according to the composition of the present invention, which is prepared by use of an alkaline-earth metal borate, is obtained by a reaction of an oil-soluble metal salt such as an oil-soluble alkaline-earth metal sulfonate, alkaline-earth metal salicylate, alkaline-earth metal phenate and alkaline-earth metal phosphonate and the like with an oxide or hydroxide of an alkaline-earth metal in the presence of boric acid or boric acid anhydride.

Examples of the alkaline-earth metal include magnesium, calcium, barium and the like, with calcium being preferred.

Among the oil-soluble metal salts, an alkaline-earth metal sulfonate is preferable in view of the good improving effects on frictional properties.

Further, it is preferable to use an overbasic oil-soluble metal salt (a) which has a base number of 100 or more, and preferably 150 or more according to the method as provided by JIS K 2501 5.2.3. Particle size of the overbasic metal salt is 0.1 μ m or less, and preferably 0.05 μ m or less.

Any methods for the preparation of the overbasic oil-soluble metal salts (a) obtained by use of an alkaline-earth metal borate may be employed. For example, the overbasic oil-soluble metal salts can be obtained by using a method which comprises reacting an oil-soluble metal salt aforesaid, a hydroxide or an oxide of alkaline-earth metal, and boric acid or boric acid anhydride in the presence of water; an alcohol such as methanol, ethanol, propanol or butanol; and a diluent such as benzene, toluene or xylene at a temperature of 20 to 200°C for 2 to 8 hours, heating the mixture to 100 to 200°C to remove water, and removing optionally the alcohol and the diluent to thereby provide an overbasic oil-soluble metal salt. The reaction conditions may be set suitably according to the raw materials employed, the amount of reactants and the like. Typical of such prior art practices are those disclosed in Japanese Patent Provisional Publication No.s 116688/60, 204298/61 and 68695/H3, and the disclosures of which are incorporated by reference.

The overbasic oil-soluble metal salt (a) thus obtained has usually a particle size of 0.1 μ m or less, and a total base number of 100 or more, and is thus preferable.

The content of overbasic oil-soluble metal salt (a), which is prepared by use of an alkaline-earth metal borate is in the range from 0.01 to 20 % by weight, preferably 0.05 to 5 % by weight on the basis of the total amount of the composition of the present invention. When the content is less than about 0.01 % by weight, the improvement effect of frictional properties is insufficient. Inversely, when the content is in excess of about 20 % by weight, no additional merits can be obtained unpreferably. Also when another overbasic oil-soluble metal salt such as those prepared by use of an alkaline-earth metal carbonate is employed instead of component (a), the composition cannot provide useful frictional properties unpreferably.

Examples of the compound used as component (b), which has a long-chain alkyl group and an amino group in the same molecular structure, are chosen from the group comprising succinimides and derivatives thereof, benzylamines, polyalkenylamines, and polyoxyalkylene aminoamides.

Typical succinimides or derivatives thereof are those prepared by a method comprising reacting a polyolefin such as polybutenes having a molecular weight of 300 to 3000 with maleic anhydride, imidating the resulting product with a polyamine such as tetraethylenepentamine, and optionally amidating a part of the residual amino groups of the resulting imide compound with an aromatic polycarboxylic acid such as phthalic acid, trimellitic acid, pyromellitic acid. The product thus obtained may be further modified with boric acid.

In the imidation, two types of imide compounds can be obtained, one of which is the so-called "mono-type" wherein one end of the polyamine molecular chain is occupied by maleic anhydride moiety, and the other is "bis-type" wherein both ends of the polyamine molecular chain are occupied by maleic anhydride moieties.

Examples of the benzylamines include those prepared by the Mannich reaction in which a polyolefin such as propylene oligomers or polybutenes having a molecular weight of 300 to 3000 is reacted with phenol, and the resulting alkylphenol is further reacted with formaldehyde and a polyamine to thereby provide a benzylamine.

Examples of the polyalkenylamine include those prepared by a method comprising chlorinating a polyolefin such

as polybutenes having a molecular weight of 300 to 3000, and then reacting the product with ammonium or a polyamine to give a polyalkenylamine.

The amount of component (b), which has a long-chain alkyl group and an amino group in the same molecular structure, may range from 0.01 to 15 % by weight, preferably 0.05 to 10 % by weight on the basis of the total amount of the composition of the present invention. When the content is less than about 0.01 % by weight, the composition of the present invention only exhibits good frictional properties for a short period of time. Inversely, when it is in excess of about 15 % by weight, no additional merits can be obtained unpreferably.

In the automatic transmission fluid composition for use in the method according to the present invention, conventional additives may arbitrarily be employed to further enhance the performances.

Examples of such additives include metallic detergents such as other alkaline-earth metal sulfonates other than those used as component (a) of the composition of the present invention, alkaline-earth metal phenates, phosphonates, carboxylates, salicylates and the like; antioxidants such as zinc alkyl or aryl dithiophosphates, hindered phenols, aromatic amines and the like; extreme pressure agents such as olefin sulfides, ester sulfides, phosphoric esters, phosphorus esters and the like; friction modifiers such as fatty acids, salts and esters of a fatty acid, higher alcohols, acid phosphoric esters, amine compounds and the like; metal deactivators; rust preventives; viscosity index improvers; pour point depressants; seal swelling agents; defoaming agents and mixtures thereof.

The viscosity index improver, defoaming agent, metal deactivator, and other additives may usually be present in the composition of the present invention in amounts of from 1 to 30 % by weight, from 0.0001 to 1 % by weight, 0.005 to 1 % by weight, and 0.1 to 15 % by weight respectively, on the basis of the total amount of composition of the present invention.

While the advantages of the composition for use in the method according to the present invention will be described in detail hereinbelow in conjunction with the following examples, it is to be noted that the scope of the present invention should not be limited to these examples.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Examples 1 to 6 and Comparative Examples 1 to 5

According to the composition of the present invention indicated in Table 1, the automatic transmission fluid compositions of the present invention were prepared. Frictional properties (μ d, μ s, μ o/ μ d) were measured at 500 cycles-hour and 10000 cycles-hour with respect to these compositions by means of SAE No.2 friction tester (with the use of commercially available paper frictional materials), and the results thereof are shown in Table 2.

For the comparison, frictional properties were also measured with respect to the compositions prepared in accordance with the composition of the present invention indicated in Table 1 wherein no component (a) is used (comparative Example 1), no component (b) is used (Comparative Example 2), a calcium sulfonate neutral salt instead of component (a) is used (Comparative Example 3), an overbasic calcium sulfonate which has been prepared by use of calcium carbonate is used instead of component (a) (Comparative Example 4) and a commercially available automatic transmission fluid composition is used (Comparative Example 5), and the results thereof are shown in Table 2.

¹⁾ Overbasic type, by use of Ca-borate ²⁾ The same as shown in Table 1 (Antioxidants, Wear preventives, Metal deactivators, VI improvers etc.) ³⁾ Neutral salt ⁴⁾ Overbasic type, by use of Ca-carbonate

As is apparent from the results of the frictional properties as shown in Tables 1 and 2, the automatic transmission

fluid compositions of Examples 1 to 6 for use in the method according to the present invention have high coefficients of dynamic friction (μ_d) and static breakaway friction (μ_s), moreover, the ratio (μ_o/μ_d) of the coefficient of friction at the end of clutch engaging to the coefficient of dynamic friction is close to 1.0. As a result, these compositions have characteristics useful for lubricating an automatic transmission according to the method of the present invention. In addition, the difference between these coefficients measured at 500 cycles-hour and at 10000 cycles-hour respectively is very small; therefore, it is also apparent that the frictional properties of these compositions for use in the method according to the present invention are also useful in that they do not change largely with time during use.

On the contrary, when the composition of Comparative Example 2 in which no component (a) is used is compared with the corresponding composition of Example 1, the μ_d decreases and the ratio μ_o/μ_d increases unpreferably. The frictional properties are also inferior to those of the composition of the present invention in that they change largely with time during use.

When the composition of Comparative Example 1 in which no component (b) is used is compared with the corresponding composition of the present invention according to Example 1, their frictional properties measured at 500 cycles-hour are nearly equal; however, the frictional properties measured at 10,000 cycles-hour is significantly impaired, showing that the frictional properties are inferior to those of the composition of the present invention in that they change largely with time during use.

When the composition of Comparative Example 3 or 4, in which a neutral calcium sulfonate or an overbasic calcium sulfonate prepared by use of calcium carbonate is used respectively, is compared with the corresponding composition of Example 1, both the μ_d and μ_s decrease and the ratio μ_o/μ_d increases, showing that these compositions are inferior to the composition of the present invention according to Example 1 in all the frictional properties.

On the other hand, the commercially available composition of Comparative Example 5 shows a μ_o/μ_d ratio and a change with time in frictional properties comparable with those of the composition of the present invention; however, the values of μ_d and μ_s decrease considerably.

As described above, effects of adding component (a) with component (b) are clear, and it is apparent that only the compositions for use in the method according to the present invention exhibit particularly superior performance.

Claims

1. A method for the lubrication of an automatic transmission of a motorcar which comprises lubricating the automatic transmission with an automatic transmission fluid composition comprising (a) 0.01 to 20% by weight of an overbasic oil-soluble metal salt prepared by reaction of a metal salt selected from an alkaline-earth metal sulphonate, an alkaline-earth metal salicylate, an alkaline-earth metal phenate and/or an alkaline-earth metal phosphonate with an oxide or hydroxide of an alkaline-earth metal in the presence of boric acid or boric acid anhydride, and (b) 0.01 to 15% by weight of a compound having a long-chain alkyl group and an amino group, chosen from succinimides and derivatives thereof, benzylamines, polyalkenylamines and polyoxyalkylene aminoamides, which have been prepared from polyolefins having a molecular weight of at least 300, on the basis of the total amount of composition as essential components, the balance being lubricating base oil.
2. A method for the lubrication of an automatic transmission of a motorcar according to claim 1, wherein said composition comprises (a) 0.05 to 5% by weight of said overbasic oil-soluble metal salt and (b) 0.05 to 10% by weight of said compound having a long-chain alkyl group and an amino group, on the basis of the total amount of composition as essential components, the balance being lubricating base oil.
3. A method for the lubrication of an automatic transmission of a motorcar according to claim 2, wherein said overbasic oil-soluble metal salt is an overbasic oil-soluble calcium salt prepared by reaction of a calcium sulphonate with a calcium oxide or hydroxide in the presence of boric acid or boric acid anhydride, and said compound having a long-chain alkyl group and an amino group is a compound chosen from succinimides and derivatives thereof, which have been prepared from polyolefins having a molecular weight of at least 300.
4. A method for the lubrication of an automatic transmission of a motorcar according to any one of claims 1 through 3, wherein said overbasic oil-soluble metal salt has a base number of 100 or more.
5. A method for the lubrication of an automatic transmission of a motorcar according to any one of claims 1 through 4, wherein the particle size of said overbasic oil-soluble metal salt is 0.1 μm or less.

Patentansprüche

1. Ein Verfahren zum Schmieren eines Automatic-Getriebes eines Kraftwagens, umfassend das Schmieren des Automatic-Getriebes mit einer flüssigen Zusammensetzung für Automatic-Getriebe, umfassend als wesentliche Komponenten (a) 0,01 bis 20Gew% eines überbasischen öllöslichen Metallsalzes, hergestellt durch das zur Reaktion bringen eines Metallsalzes, ausgewählt aus einem Erdalkalimetallsulfonat, einem Erdalkalimetallsalicylat, einem Erdalkalimetallphenat und/oder einem Erdalkalimetallphosphonat, mit einem Oxid oder Hydroxid eines Erdalkalimetalls in Gegenwart von Borsäure oder Borsäureanhydrid, und (b) 0,01 bis 15Gew% einer Verbindung mit einer langkettigen Alkylgruppe und einer Aminogruppe, ausgewählt aus Succinimiden und deren Derivaten, Benzylaminen, Polyalkenylaminen und Polyoxyalkylenamincamiden, welche aus Polyolefinen mit einem Molekulargewicht von mindestens 300 hergestellt worden sind, jeweils auf Basis der Gesamtmenge der Zusammensetzung, wobei die Restmenge ein Grundschmieröl ist.
2. Ein Verfahren zum Schmieren eines Automatic-Getriebes eines Kraftwagens gemäß Anspruch 1, in welchem die besagte Zusammensetzung als wesentliche Komponenten (a) 0,05 bis 5Gew% des besagten überbasischen öllöslichen Metallsalzes und (b) 0,05 bis 10Gew% der besagten Verbindung mit einer langkettigen Alkylgruppe und einer Aminogruppe umfaßt, und zwar auf Basis der Gesamtmenge der Zusammensetzung, wobei die Restmenge ein Grundschmieröl ist.
3. Ein Verfahren zum Schmieren eines Automatic-Getriebes eines Kraftwagens gemäß Anspruch 2, in welchem das besagte überbasische öllösliche Metallsalz ein überbasisches öllösliches Kalziumsalz ist, welches durch das zur Reaktion bringen eines Kalziumsulfonats mit einem Kalziumoxid oder -hydroxid in Gegenwart von Borsäure oder Borsäureanhydrid hergestellt worden ist, und die besagte Verbindung mit einer langkettigen Alkylgruppe und einer Aminogruppe eine Verbindung ist, die ausgewählt ist aus Succinimiden und deren Derivaten, welche aus Polyolefinen mit einem Molekulargewicht von mindestens 300 hergestellt worden sind.
4. Ein Verfahren zum Schmieren eines Automatic-Getriebes eines Kraftwagens gemäß einem der Ansprüche 1 bis 3, in welchem das besagte überbasische öllösliche Metallsalz eine Basenzahl von 100 oder mehr aufweist.
5. Ein Verfahren zum Schmieren eines Automatic-Getriebes eines Kraftwagens gemäß einem der Ansprüche 1 bis 4, in welchem die Teilchengröße von besagtem überbasischen öllöslichen Metallsalz 0,1 µm oder weniger beträgt.

Revendications

1. Méthode de lubrification d'une transmission automatique de voiture consistant à lubrifier la transmission automatique avec un fluide pour transmission automatique qui comporte (a) de 0,01 à 20 % en poids d'un sel métallique surbasique soluble dans l'huile préparé par réaction d'un sel métallique choisi parmi un sulfonate d'un métal alcalino-terreux, un salicylate d'un métal alcalino-terreux, un phénate d'un métal alcalino-terreux et/ou un phosphonate d'un métal alcalino-terreux avec un oxyde ou un hydroxyde d'un métal alcalino-terreux en présence d'acide borique ou d'anhydride borique, et (b) de 0,01 à 15 % en poids d'un composé ayant un groupe alkyle à longue chaîne et un groupe amino choisi parmi les succinimides et les dérivés de ces derniers, les benzylamines, les polyalkylèneamines et les aminoamides de polyoxyalkylène, qui ont été préparés à partir de polyoléfines de poids moléculaire d'au moins 300, par rapport à la quantité totale des composants essentiels, le complément étant assuré par l'huile de base lubrifiante.
2. Méthode de lubrification d'une transmission automatique d'une voiture selon la revendication 1, caractérisée en ce que ladite composition comporte (a) de 0,05 à 5 % en poids dudit sel métallique surbasique soluble dans l'huile et (b) de 0,05 à 10 % en poids dudit composé ayant un groupe alkyle à longue chaîne et un groupe amino, par rapport à la quantité totale des composants essentiels, le complément étant assuré par l'huile de base lubrifiante.
3. Méthode de lubrification d'une transmission automatique d'une voiture selon la revendication 2, caractérisée en ce que ledit sel métallique surbasique soluble dans l'huile est un sel de calcium surbasique soluble dans l'huile préparé par réaction d'un sulfonate de calcium avec un oxyde ou un hydroxyde de calcium en présence d'acide ou d'anhydride borique, et ledit composé ayant un groupe alkyle à longue chaîne et un groupe amino est un composé choisi parmi les succinimides et les dérivés de ces derniers, qui ont été préparés à partir de polyoléfines de poids moléculaire d'au moins 300.

EP 0 544 298 B1

4. Méthode de lubrification d'une transmission automatique d'une voiture selon l'une quelconque des revendications 1 à 3, caractérisée en ce que ledit sel métallique surbasique soluble dans l'huile a un indice de base de 100 ou plus.
5. Méthode de lubrification d'une transmission automatique d'une voiture selon l'une quelconque des revendications 1 à 4, caractérisée en ce que la taille des particules dudit sel métallique surbasique soluble dans l'huile est de 0,1 μm ou moins.
